# **Recurrent Neural Networks**

LATEST SUBMISSION GRADE

100%

1. Suppose your training examples are sentences (sequences of words). Which of the following refers to the  $j^{th}$  word in the

1 / 1 point

- $\bigcirc \ x^{< i > (j)}$
- $\bigcirc \ x^{(j) < i >}$
- $\bigcap x^{< j > (i)}$

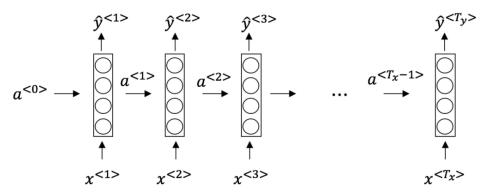

### ✓ Correct

We index into the  $i^{th}$  row first to get the  $i^{th}$  training example (represented by parentheses), then the  $j^{th}$ column to get the  $j^{th}$  word (represented by the brackets).

2. Consider this RNN:

1 / 1 point

This specific type of architecture is appropriate when:

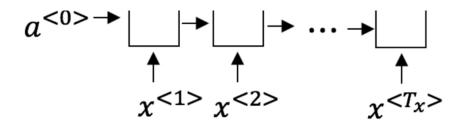

- $T_x = T_y$
- $\bigcap T_x < T_y$
- $\bigcap T_x > T_y$
- $\bigcap T_x = 1$

It is appropriate when every input should be matched to an output.

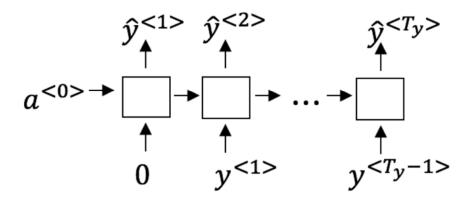

3. To which of these tasks would you apply a many-to-one RNN architecture? (Check all that apply).

- Speech recognition (input an audio clip and output a transcript)
- Sentiment classification (input a piece of text and output a 0/1 to denote positive or negative sentiment)
  - ✓ Correct!
- ☐ Image classification (input an image and output a label)
- Gender recognition from speech (input an audio clip and output a label indicating the speaker's gender)
  - ✓ Correct!
- 4. You are training this RNN language model.

1/1 point

At the  $t^{th}$  time step, what is the RNN doing? Choose the best answer.

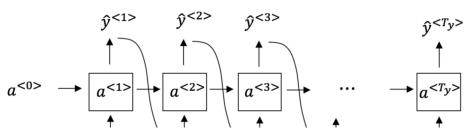

- $\bigcirc \ \, \operatorname{Estimating} P(y^{<1>},y^{<2>},\dots,y^{< t-1>})$
- $\bigcirc \ \ \text{Estimating} \ P(y^{< t>})$
- Estimating  $P(y^{< t>} \mid y^{< 1>}, y^{< 2>}, \ldots, y^{< t-1>})$
- $\bigcirc \ \, \text{Estimating} \, P(y^{< t>} \mid y^{< 1>}, y^{< 2>}, \ldots, y^{< t>})$

#### Correct

Yes, in a language model we try to predict the next step based on the knowledge of all prior steps.

 $5. \quad You \ have \ finished \ training \ a \ language \ model \ RNN \ and \ are \ using \ it \ to \ sample \ random \ sentences, \ as \ follows:$ 

1 / 1 point

What are you doing at each time step t?

- (i) Use the probabilities output by the RNN to pick the highest probability word for that time-step as  $\hat{y}^{< t>}$ . (ii) Then pass the ground-truth word from the training set to the next time-step.
- (i) Use the probabilities output by the RNN to randomly sample a chosen word for that time-step as  $\hat{y}^{< t>}$ .(ii) Then pass the ground-truth word from the training set to the next time-step.
- (i) Use the probabilities output by the RNN to pick the highest probability word for that time-step as  $\hat{y}^{< t>}$ .(ii) Then pass this selected word to the next time-step.
- (i) Use the probabilities output by the RNN to randomly sample a chosen word for that time-step as  $\hat{y}^{< t>}$ .(ii) Then pass this selected word to the next time-step.

✓ Correct

6. You are training an RNN, and find that your weights and activations are all taking on the value of NaN ("Not a Number"). Which of these is the most likely cause of this problem?

1 / 1 point

- O Vanishing gradient problem.
- Exploding gradient problem.
- ReLU activation function g(.) used to compute g(z), where z is too large.
- Sigmoid activation function g(.) used to compute g(z), where z is too large.

✓ Correct

7. Suppose you are training a LSTM. You have a 10000 word vocabulary, and are using an LSTM with 100-dimensional activations  $a^{< t>}$ . What is the dimension of  $\Gamma_u$  at each time step?

1/1 point

- $\bigcirc$  1
- 100
- O 300
- 0 10000

✓ Correct

Correct,  $\Gamma_u$  is a vector of dimension equal to the number of hidden units in the LSTM.

8. Here're the update equations for the GRU.

1 / 1 point

**GRU** 

$$\tilde{c}^{< t>} = \tanh(W_c[\Gamma_r * c^{< t-1>}, x^{< t>}] + b_c)$$

$$\Gamma_u = \sigma(W_u[c^{< t-1>}, x^{< t>}] + b_u)$$

$$\Gamma_r = \sigma(W_r[c^{< t-1>}, x^{< t>}] + b_r)$$

$$c^{} = \Gamma_u * \tilde{c}^{} + (1 - \Gamma_u) * c^{}$$

$$a^{< t>} = c^{< t>}$$

Alice proposes to simplify the GRU by always removing the  $\Gamma_u$ . I.e., setting  $\Gamma_u$  = 1. Betty proposes to simplify the GRU by removing the  $\Gamma_r$ . I. e., setting  $\Gamma_r$  = 1 always. Which of these models is more likely to work without vanishing gradient problems even when trained on very long input sequences?

igcap Alice's model (removing  $\Gamma_{\rm e}$ ) because if  $\Gamma_{\rm e} pprox 0$  for a timesten, the gradient can propagate back through that

	timestep without much decay.	the gradient can propagate sact through that	
	$\bigcirc$ Alice's model (removing $\Gamma_u$ ), because if $\Gamma_r \approx 1$ for a timestep, the gradient can propagate back through that timestep without much decay.		
	$igotimes$ Betty's model (removing $\Gamma_r$ ), because if $\Gamma_u pprox 0$ for a timestep, the gradient can propagate back through that timestep without much decay.		
	O Betty's model (removing $\Gamma_r$ ), because if $\Gamma_u \approx 1$ for a timestep, the gradient can propagate back through that timestep without much decay.		
	$\checkmark$ Correct Yes. For the signal to backpropagate without vanishing, we need $c^{< t>}$ to be highly dependent on $c^{< t-1>}$ .		
9.	Here are the equations for the GRU and the LSTM:		1/1 point
	GRU	LSTM	
	$\tilde{c}^{< t>} = \tanh(W_c[\Gamma_r * c^{< t-1>}, x^{< t>}] + b_c)$	$\tilde{c}^{< t>} = \tanh(W_c[a^{< t-1>}, x^{< t>}] + b_c)$	
	$\Gamma_u = \sigma(W_u[c^{< t-1>}, x^{< t>}] + b_u)$	$\Gamma_u = \sigma(W_u[a^{< t-1>},x^{< t>}] + b_u)$	
	$\Gamma_r = \sigma(W_r[c^{< t-1>},x^{< t>}] + b_r)$	$\Gamma_f = \sigma(W_f[a^{< t-1>},x^{< t>}] + b_f)$	
	$c^{< t>} = \Gamma_u * \tilde{c}^{< t>} + (1 - \Gamma_u) * c^{< t-1>}$	$\Gamma_o = \sigma(W_o[\ a^{< t-1>}, x^{< t>}] + b_o)$	
	$a^{} = c^{}$	$c^{< t>} = \Gamma_u * \tilde{c}^{< t>} + \Gamma_f * c^{< t-1>}$	
		$a^{< t>} = \Gamma_o * c^{< t>}$	
	From these, we can see that the Update Gate and Forget Gate in the LSTM play a role similar to and in the GRU. What should go in the blanks?		
	$igotimes \Gamma_u$ and $1-\Gamma_u$		
	$igcap \Gamma_u$ and $\Gamma_r$		
	$igcap 1 - \Gamma_u$ and $\Gamma_u$		
	$igcap \Gamma_r$ and $\Gamma_u$		
	✓ Correct  Yes, correct!		
10.	0. You have a pet dog whose mood is heavily dependent on the current and past few days' weather. You've collected data for the past 365 days on the weather, which you represent as a sequence as $x^{<1>},\ldots,x^{<365>}$ . You've also collected data on your dog's mood, which you represent as $y^{<1>},\ldots,y^{<365>}$ . You'd like to build a model to map from $x\to y$ . Should you use a Unidirectional RNN or Bidirectional RNN for this problem?		1/1 point
	Bidirectional RNN, because this allows the prediction of mood on day t to take into account more information.		
	Bidirectional RNN, because this allows backpropagation to compute more accurate gradients.		
	$igoplus Unidirectional RNN, because the value of y^{< t>} depends only of y^{< t} depends only of $		
	O Unidirectional RNN, because the value of $y^{< t>}$ depends only of	on $x^{< t>}$ , and not other days' weather.	

✓ Correct Yes!
